

## Lecture 8: Hypothesis Testing (contd.)

### Defn (Best critical region of size $\alpha$ )

Consider the test of the simple null hypothesis

$$H_0: \theta = \theta_0 \text{ vs } H_a: \theta = \theta_1$$

Let  $C$  be a critical region of size  $\alpha$ , i.e.

$$\alpha = P[(X_1, X_2, \dots, X_n) \in C; \theta_0]. \text{ Then } C \text{ is}$$

a best critical region of size  $\alpha$  if, for

every other critical region  $D$  of size  $\alpha$ ,

$$\text{i.e. } \alpha = P[(X_1, X_2, X_3, \dots, X_n) \in D; \theta_0], \text{ we}$$

$$\text{have } P[(X_1, X_2, \dots, X_n) \in C; \theta_1] \geq$$

$$P[(X_1, X_2, \dots, X_n) \in D; \theta_1]$$

That is, when  $H_a: \theta = \theta_1$  is true, the probability of rejecting  $H_0: \theta = \theta_0$  with

the use of the critical region  $C$  is at least as great as the corresponding probability with the use of any other critical region  $D$  of size  $\alpha$ .

### Example 1:

Let  $X_1, X_2, \dots, X_n$  be a random sample of size  $n$  from a Poisson distribution with mean  $\lambda$ . A BCR for testing

$H_0: \lambda = 2$  vs  $H_a: \lambda = 5$  is given by

$$\frac{L(\lambda=5)}{L(\lambda=2)} = \frac{5^{\sum x_i} e^{-5n}}{2^{\sum x_i} e^{-2n}} \frac{x_1! x_2! \dots x_n!}{x_1! x_2! \dots x_n!} > K$$

$$\Rightarrow \left(\frac{5}{2}\right)^{\sum x_i} e^{-3n} > K$$

$$\Rightarrow \sum x_i \ln(5/2) - 3n > \ln K$$

$$\Rightarrow \sum x_i > \frac{\ln K + 3n}{\ln(5/2)} = c$$

### Defn (Uniformly Most Powerful Test)

A test defined by a critical region  $C$  of size  $\alpha$  is a uniformly most powerful test (UMPT) if it is a most powerful test against each simple alternative in  $H_a$ . The critical region  $C$  is called a uniformly most powerful critical region of size  $\alpha$ .

## Example 2

Let  $X_1, X_2, \dots, X_n$  be a random sample from  $N(\mu, 36)$ . Consider  $H_0: \mu = 50$  vs  $H_a: \mu = 55$

A BCR of size  $\alpha$  is given by

$C = \{ (x_1, x_2, \dots, x_n) : \bar{x} > c \}$ , where  $c$  is selected so that the significance level is  $\alpha$ . Now consider testing

$H_0: \mu = 50$  vs  $H_a: \mu > 50$

For each simple hypothesis  $H_a: \mu = \mu_1 > 50$

$$\frac{L(\mu = \mu_1)}{L(\mu = 50)} = \exp \left\{ \frac{-1}{72} \left( 2 \sum x_i (50 - \mu_1) + n(\mu_1^2 - 50^2) \right) \right\} > k$$

$$\Rightarrow -\frac{1}{72} \left( 2 \sum x_i (50 - \mu_1) + n(\mu_1^2 - 50^2) \right) > \ln k$$

$$\Rightarrow \bar{x} > \frac{72 \ln k}{2n(\mu_1 - 50)} + \frac{\mu_1 - 50}{2} = c.$$

$$\therefore \bar{x} > c$$

## Exercise

Let  $X_1, X_2, \dots, X_n$  be a random sample of Bernoulli trials  $b(1, p)$ .

a) Show that a BCR for testing  $H_0: p = 0.9$  against  $H_a: p = 0.8$  can be based on the statistic  $Y = \sum_{i=1}^n X_i$ , which is distributed as  $b(n, p)$

b) If  $C = \{(x_1, x_2, \dots, x_n): \sum_{i=1}^n x_i \leq n(0.85)\}$  and  $Y = \sum_{i=1}^n X_i$ , find the value of  $n$  such that  $\alpha = P[Y \leq n(0.85); p = 0.9] \approx 0.10$

(Hint: Use the normal approximation for the binomial distribution)

c) What is the approximate value of  $\beta = P[Y > n(0.85); p = 0.8]$  for the test given in part (b)?

d) Is the test of part (b) a uniformly most powerful test when the alternative is  $H_a: p < 0.9$ ?

### Likelihood Ratio Tests

A more general test-construction method applicable when either or both of the null and alternative are composite.

Let  $\Omega$  denote the total parameter space.

Let  $H_0: \theta \in \omega$  vs  $H_a: \theta \in \omega'$

Defn (Likelihood Ratio):

$$\lambda = \frac{L(\hat{\omega})}{L(\hat{\Omega})} \quad \text{where } L(\hat{\omega}) = \max L \text{ under } H_0$$

$$\text{and } L(\hat{\Omega}) = \max_{\theta \in \Omega} L$$

Note that  $0 \leq \lambda \leq 1$ . Small values of  $\lambda$

would lead to the rejection of  $H_0$  and

values close to 1 would support  $H_0$ .

### Defn (Critical Region for LRT)

The set of points in the sample space for which  $\lambda \leq k$ , where  $0 < k < 1$ . Here  $k$  is selected so that a desired significance level  $\alpha$  is achieved.

### Example 3

Let  $X \sim N(\mu, 5)$  and  $H_0: \mu = 162$  vs  $H_a: \mu \neq 162$ .

$$\Omega = \{\mu: -\infty < \mu < \infty\} \text{ and } \omega = \{162\}.$$

$$\lambda = \frac{L(\hat{\omega})}{L(\hat{\Omega})} = \frac{L(162)}{L(\bar{x})}, \text{ since } \hat{\mu} = \bar{x}$$

$$= \frac{\exp\left[-\left(\frac{1}{10}\right) \sum (x_i - \bar{x})^2 - \left(\frac{n}{10}\right) (\bar{x} - 162)^2\right]}{\exp\left[-\left(\frac{1}{10}\right) \sum (x_i - \bar{x})^2\right]}$$

$$\exp\left[-\left(\frac{1}{10}\right) \sum (x_i - \bar{x})^2\right]$$

$$= \exp\left[-\left(\frac{n}{10}\right) (\bar{x} - 162)^2\right] \leq k$$

$$\Rightarrow -\left(\frac{n}{10}\right) (\bar{x} - 162)^2 \leq \ln k$$

$$\Rightarrow \frac{|\bar{x} - 162|}{\sqrt{5/n}} \geq \frac{\sqrt{-(10/n) \ln k}}{\sqrt{5/n}} = c$$

Since  $Z = (\bar{X} - 162) / \sqrt{S/n} \sim N(0, 1)$  under  $H_0$ ,

let  $c = z_{\alpha/2}$ . Thus,  $C = \left\{ \bar{x} : \frac{|\bar{x} - 162|}{\sqrt{S/n}} \geq z_{\alpha/2} \right\}$

For  $\alpha = 0.05$ ,  $z_{\alpha/2} = 1.96$ .

Now, suppose  $X \sim N(\mu, \sigma^2)$ , ( $\mu, \sigma^2$  unknown).

To test  $H_0: \mu = \mu_0$  vs  $H_a: \mu \neq \mu_0$ ,

define  $\omega = \{(\mu, \sigma^2) : \mu = \mu_0, 0 < \sigma^2 < \infty\}$

$\Omega = \{(\mu, \sigma^2) : -\infty < \mu < \infty, 0 < \sigma^2 < \infty\}$

$$L(\hat{\omega}) = \left( \frac{n e^{-1}}{2\pi \sum (x_i - \bar{x})^2} \right)^{n/2}$$

$$L(\hat{\omega}) = \left( \frac{n e^{-1}}{2\pi \sum (x_i - \mu_0)^2} \right)^{n/2}$$

$$\Rightarrow \lambda = L(\hat{\omega}) / L(\hat{\omega}) = \left( \frac{\sum (x_i - \bar{x})^2}{\sum (x_i - \mu_0)^2} \right)^{n/2}$$

$$= \left[ \frac{\sum (x_i - \bar{x})^2}{\sum (x_i - \bar{x})^2 + n(\bar{x} - \mu_0)^2} \right]^{n/2}$$

$$= \left[ \frac{1}{1 + \frac{n(\bar{x} - \mu_0)^2}{\sum (x_i - \bar{x})^2}} \right]^{n/2}$$

$$\Rightarrow \frac{1}{1 + \frac{n(\bar{x} - \mu_0)^2}{\sum (x_i - \bar{x})^2}} \leq K^{2/n}$$

$$\Rightarrow \frac{n(\bar{x} - \mu_0)^2}{\frac{1}{n-1} \sum (x_i - \bar{x})^2} \geq (n-1)(K^{-2/n} - 1)$$

Under  $H_0$ ,  $\sqrt{n}(\bar{x} - \mu_0)/\sigma \sim N(0, 1)$

and  $\sum (x_i - \bar{x})^2/\sigma^2 \sim \chi^2(n-1)$

$$\therefore T = \frac{n(\bar{x} - \mu_0)/\sigma}{\sqrt{\sum (x_i - \bar{x})^2/(n-1)\sigma^2}} = \frac{\bar{x} - \mu_0}{S/\sqrt{n}}$$

has a  $t(n-1)$  distribution

So we reject  $H_0$  if  $T^2 \geq (n-1)(K^{-2/n} - 1)$

i.e.  $|T| \geq t_{\alpha/2}(n-1)$ .

### Exercise (fill in missing steps)

Let  $X \sim N(\mu, \sigma^2)$ , where both  $\mu$  and  $\sigma^2$  are unknown.

Let  $H_0: \sigma^2 = \sigma_0^2$  vs  $H_a: \sigma^2 \neq \sigma_0^2$

Here  $\omega = \{(\mu, \sigma^2): -\infty < \mu < \infty, \sigma^2 = \sigma_0^2\}$

$\Omega = \{(\mu, \sigma^2): -\infty < \mu < \infty, 0 < \sigma^2 < \infty\}$

$$L(\hat{\Omega}) = \left( \frac{n e^{-1}}{2\pi \sum (x_i - \bar{x})^2} \right)^{n/2}$$

$$L(\hat{\omega}) = \left( \frac{1}{2\pi\sigma_0^2} \right)^{n/2} \exp \left[ -\frac{\sum (x_i - \bar{x})^2}{2\sigma_0^2} \right]$$

$$\lambda = L(\hat{\omega}) / L(\hat{\Omega})$$

$$= \left( \frac{v}{n} \right)^{n/2} \exp \left( -\frac{v}{2} + \frac{n}{2} \right) \leq \kappa \quad \text{--- (1)}$$

where  $v = \sum (x_i - \bar{x})^2 / \sigma_0^2$

Solving (1) for  $v \Rightarrow v \leq c_1$  or  $v \geq c_2$

But  $V = \sum_{i=1}^n (X_i - \bar{X})^2 / \sigma_0^2 \sim \chi^2(n-1)$  under  $H_0$ .

Thus  $c_1 = \chi^2_{1-\alpha/2}(n-1)$  and  $c_2 = \chi^2_{\alpha/2}(n-1)$ .

Exercise

Let  $X_1, X_2, \dots, X_n$  be a random sample from the exponential distribution with mean  $\theta$ . Show that the likelihood ratio test of

$H_0: \theta = \theta_0$  vs  $H_a: \theta \neq \theta_0$   
has a critical region of the form

$$\sum_{i=1}^n x_i \leq c_1 \text{ or } \sum_{i=1}^n x_i \geq c_2.$$

How would you modify this test so that chi-square tables can be used easily?
